Attempt all the questions!

Tasks:

1. A transport company wants to identify passengers living in Karachi for a special discount campaign. Write a query to display the name and phone number of all users who live in Karachi.
2. The operations department needs a combined report showing which passengers traveled with which driver along with the fare charged for each trip. Write a query to display the user name, driver name, and fare for each ride.
3. The system administrator decides that every driver must have an email address recorded, and no two drivers can share the same email. Also, every driver record must include this information. Write an SQL statement to add an email field to the Drivers table ensuring it is always filled and unique.
4. The customer support team wants a cleaner vehicle report where all vehicle models appear in uppercase and only the last part of the plate number is shown instead of the full value. Write a query to display vehicle models in uppercase and a shortened version of their plate numbers.
5. The finance department wants to identify which pickup locations generate high revenue so they can focus on those areas, but only locations that earn significant total revenue should be shown. Write a query to calculate total fare per pickup location and show only those locations where earnings are greater than 400.
6. The marketing team wants to reward users who have taken expensive rides compared to the overall average trip cost in the system. Write a query to find the names of users whose ride fares are higher than the average fare of all rides.
7. The operations team regularly needs a single consolidated report showing which driver is assigned to which vehicle along with vehicle details. Create a view that displays driver name, vehicle model, and plate number.
8. The company wants to automatically keep a record of every time a driver's status is changed, so that each change is stored in a separate history table without modifying any existing driver data.
Hint: First create a history table to store driver status changes, then create a trigger that automatically inserts records into this table whenever a driver's status is updated.
